

Room Task

1. Task 3:

To create a Selenium framework that can handle changes in the application language, you can follow the steps below:

1. Separate test data and test scripts: Create a separate file or database to store test data and ensure that all test scripts reference this external data source. This will make it easier to update test data in case of a language change.
2. Use locators with variables: Instead of hardcoding locators in your test scripts, use variables to represent locators. This will allow you to easily update locators when the application language changes.
3. Use parameterization: Parameterize your test scripts to make them language-independent. Use variables for text inputs, error messages, and other language-specific elements.
4. Implement language support in your framework: Create a language support module in your framework that can dynamically switch between different languages. This module should be able to load language-specific resource files and update test data and locators accordingly.
5. Use assertions with dynamic text validation: Instead of hardcoded text in assertions, use dynamic text validation that can handle variations in language. For example, you can use regular expressions to match text patterns instead of exact text.
6. Use a language-neutral test strategy: Design your test scenarios in a way that they are not dependent on the specific language of the application. Focus on testing functionality and logic rather than language-specific elements.

By following these steps, you can create a Selenium framework that can handle changes in the application language and enable your tests and assertions to pass seamlessly. This will help you maintain the reliability and efficiency of your test automation suite even when the application language changes.

2. Task 4 - Perform exploratory testing and write a bug report for any one of the identified bugs:

1.
